

**ORALLY DISINTEGRATING TABLETS AND METHODS OF MANUFACTURE**

**FIELD OF THE INVENTION**

**[0001]** The present invention relates to orally disintegrating tablets and a method for their manufacture. More particularly it relates to an orally disintegrating tablet made up of rapidly dispersing microgranules and taste-masked microcapsules.

**[0002]** Another embodiment of the invention relates to a tablet, which is compressed into a predetermined shape after blending the granulated material with a suitable lubricant. An ideal orally disintegrating tablet formulation rapidly disintegrates in the buccal cavity dispersing the contents and has a pleasant taste and smooth creamy mouthfeel (no grittiness), and complete drug release occurs in the gastrointestinal tract so as to be bioequivalent to the reference immediate release product. This convenience leads to better compliance with dosing regimen and as a consequence, to enhanced therapy. From an industrial/commercial utility point of view, the tablets should have sufficient strength to be suitable for packaging in HDPE bottles and push-through blisters for storage, transportation and distribution.

**[0003]** There are two types of most widely used dosage forms for oral administration: tablets and capsules. However, such dosage forms have several common disadvantages. For example, it may be hard for aged persons to swallow tablets or capsules or to medicate children who are unwilling to swallow tablets or capsules. It is also inconvenient for the 'people on the move' to take such dosage forms since they need to look for water. On the other hand, solid medicines, which rapidly dissolve or disintegrate in the buccal cavity, can be taken without water, so they may be easily taken by such aged persons, children or the 'people on the move'.

**[0004]** Different types of dosage forms disintegrating/dissolving rapidly in the buccal cavity have been developed and dosage forms comprising a number of actives are commercially available to enhance patient compliance. For instance, in JP-B-62-50445, solid dosage forms which can be produced from aqueous solutions containing gelatin and an active ingredient by freeze drying are disclosed. And in WO93/12769, solid medicines which can be produced by drying suspension including agar are also disclosed. However, the medicines produced by the above-mentioned prior methods do not have enough hardness for packaging in bottles or blisters

for storage, transport and commercial distribution. Hence, they require special pharmaceutical techniques and hence, require huge investments in plants and equipment.

**[0005]** Three US patents (USP 4,305,502, 4,371,516, and 5,738,875) assigned to R.P. Scherer discloses Zydis technology based on freeze-drying, which is used to manufacture rapidly dissolving tablets. The potential drug should have a particle size <50  $\mu$ m and should not have a bitter taste. Although the process is quite popular in the pharmaceutical industry, it is expensive and time-consuming. The products produced by this technology are fragile and require special packaging and handling. USP 5,178,878, 6,269,615 and 6,221,392, all assigned to Cima Labs, Inc., teach the art of manufacturing friable orally disintegrating tablets by direct compression and packaging in specially designed dome-shaped blister package using a robot-controlled integrated tabletting-packaging system. US Patents 5,464,632 and 6,106,861 disclose methods of producing rapidly disintegrating multiparticulate tablets which disintegrate in the mouth within 60 seconds comprising an active in the form of microcrystals, coated microgranules or uncoated microgranules, 3 to 15% disintegrant, 40 to 90% of a soluble diluent which is a mixture of directly compressible polyols with an average particle size of 100 to 500  $\mu$  and powdered polyols with an average particle size of less than 100  $\mu$ .

**[0006]** Takeda Chemical Industries (EP 0,553,777 A2 and USP 5,720,974) disclose production methods wherein tablets composed of a saccharide are produced in such a manner that a saccharide mixture supplied with appropriate water is compressed at a low pressure and then dried to make solid tablets. However, such methods also require a special pharmaceutical technique and have the fear that powder composing the tablets may be adhered to the surface of a metal mold in compression process under moistening condition. It may be therefore difficult to utilize those methods in manufacturing use in a plant. Furthermore, such dosage forms require well taste masked drug particles.

**[0007]** Mizumoto et al. (USP 5,576,014) have classified sugar-based excipients into two types on the basis of their moldability and dissolution rate. The moldability of a low molding sugar such as mannitol is improved by granulating with a high molding excipient and this is the basis of WOWTAB technology. Ethypharma has introduced an orally dispersible Flash Dose

technology, which contains coated crystals and microgranules along with disintegrants, a soluble diluent, a lubricant and optionally a swelling agent (EP 1156786 and WO 2002085336 A1).

**[0008]** US Patent Application No. 200100114340 published on August 16, 2001 and EP Application No. EP 0 914818 A1 published on 12/05/1999, disclose a simple method for manufacturing tablets rapidly disintegrating/dissolving in the buccal cavity by granulating widely used excipients (a sugar alcohol or saccharide such as mannitol or lactose, a disintegrant such as crospovidone) optionally with an active to produce soft dispersible microgranules, blending with other excipients and compressing into rapidly disintegrating tablets using conventional granulating, drying and tableting equipment. These and additional embodiments are disclosed in US Patent Application No. 10/356,641. A group of patents (JP 2681601, US Patent 5700492, EP 650826) disclose a method of manufacturing tablets disintegrating in the buccal cavity in less than 60 seconds, the tablet being further characterized in that it is formed by compressing in a tableting machine using a punch and a die that have been previously coated with a lubricant, the tablet formulation otherwise being free of lubricant. Eurand has licensed both these technologies from Kyowa Hakko Kogyo Company in Japan and are incorporated in their entirety by reference. The compression blends to be tableted are typically pre-blended with lubricants such as magnesium stearate and stearic acid which being highly hydrophobic retard water penetration into the tablet and hence may delay its disintegration/dissolution especially in the buccal cavity. The use of externally lubricated punches and dies and rapidly dispersing microgranules disclosed in these patents and patent applications significantly improve the disintegration properties of tablets containing high doses of taste-masked actives with a bitter taste. Furthermore, these tablets are suitable for packaging in HDPE bottles and in blister packs using conventional equipment for storage, transportation and commercial distribution.

**[0009]** Many of the active pharmaceutical ingredients are bitter in taste and require effective taste-masking before they can be incorporated into tablets which rapidly disintegrate/disperse in the buccal cavity. Another requirement for being incorporated into rapidly disintegrating tablets is that the taste-masked microcapsules/granules should be smaller than 500  $\mu\text{m}$  in diameter, preferably be smaller than 400  $\mu\text{m}$  in diameter to avoid gritty mouthfeel.

**[0010]** US Patents 5,075,114 assigned to Roche, 5,082,669 assigned to Shirai et al., 4,389,330 to Tice et al., and 4,389,331 and 4,542,042 assigned to Samejima et al. disclose methods of taste-masking using a variety of techniques. However, these methods have several limitations including forming large agglomerations and improper coating (and hence poor taste-masking).

**[0011]** WO 94/08576 with a priority date of 16 October, 1992 discloses a composition which is substantially free of the bitter taste of ranitidine HCl and comprises particles comprising ranitidine HCl incorporated into a core and coated with a lipid coating, wherein the poorly water soluble core is prepared by dispersing ranitidine HCl in an ethylcellulose solution in methylene chloride or in molten carnauba wax and the lipid is typically a mixture of mono-, di- or triester or glycerol. The tablet comprising the taste-masked ranitidine has an unacceptable drug load of 5-10% w/w.

**[0012]** US Patent 6,139,865 assigned to Eurand discloses a method of taste-masking a bitter drug such as ranitidine hydrochloride by coacervation in a cyclohexane solution containing ethylcellulose and polyethylene as a phase inducer. The microcapsules thus produced are successfully incorporated in effervescent tablet formulations exhibiting acceptable taste-masking, aftertaste, and overall acceptance characteristics. For use in an orally disintegrating tablet, the particle size of most of the taste-masked microcapsules should be less than 400  $\mu\text{m}$  or less to avoid gritty mouthfeel. This translates into a desired particle size distribution for the active in the range of 75-200  $\mu\text{m}$ . It is often difficult if not impossible in some cases to produce active drug particles with narrow size distributions. Often, the actives contain fines (under sized particles) as well as over sized particles. In order to better control the particle shape and size distribution of the active pharmaceutical ingredient, the active is milled or micronized. It is a challenge to taste mask such fine powders. The ordinary wet granulation methods using a widely used binder such as Povidone (polyvinylpyrrolidone) produce fragile/friable granules, which break down or fracture due to rapid agitation during microencapsulation by coacervation. The use of widely used binders at high concentrations results in large oversized granules, which produce fines during dry milling, and hence are not suitable for taste masking by coacervation. The present invention provides a method for the manufacture of resilient microgranules with most desired particle size distributions, which are suitable for effectively taste-masking by coacervation in accordance with methods disclosed in USP 6,139,865, which is incorporated in

its entirety by reference. The present invention also provides a method for manufacturing tablets, which rapidly disintegrate in the buccal cavity. USP 5,700,492 and EP 650826 and US Patent Application No. 20010014340 published on August 16, 2001 and EP Application No. EP 0 914818 A1 published on December 5, 1999, which were licensed to Eurand were incorporated in their entirety by reference.

#### SUMMARY OF THE INVENTION

**[0013]** Microgranules suitable for microencapsulation by coacervation should have sufficient strength and sufficiently low friability to withstand attrition caused by agitation during microencapsulation. At the same time, these microcapsules following microencapsulation should be capable of being compacted into tablets with minimal membrane fracture as membrane fracture results in undesired drug release causing bitter taste.

**[0014]** One embodiment of this invention relates to pharmaceutical compositions comprising rapidly dispersing microgranules of a disintegrant and sugar alcohol or a saccharide whose average particle size is not more than 30  $\mu\text{m}$ , resilient (hard, flexible, less-friable) microgranules of bitter active pharmaceutical ingredients effectively taste-masked by coacervation, and other pharmaceutically acceptable excipients in the form of tablets which rapidly disintegrate in the buccal cavity. Another embodiment of the invention additionally provides a method of manufacturing rapidly disintegrating microgranules of a sugar alcohol or a saccharide in combination with a disintegrant, resilient microgranules taste-masked by coacervation, and compressing these two granules along with other excipients such as color, flavor, sweetener, into tablets, the tablet thus produced having the property that it is formed by compressing in a tablet press equipped with an externally lubricating system to pre-lubricate dies and punches and the tablet formulation otherwise being free of lubricant.

**[0015]** In accordance with the one embodiment of the invention, milled/micronized drug particles (e.g., average particle diameter less than about 50  $\mu\text{m}$ , preferably less than about 25  $\mu\text{m}$ ) are blended with a water soluble ductile polymeric binder such as modified starch and hydroxypropyl methylcellulose with a viscosity of 100 cps or higher, alone or in combination with a widely used binder such as PVP (polyvinylpyrrolidone), hydroxypropylcellulose and hydroxypropyl methylcellulose with a viscosity of 15 cps or less. This wet mass is milled using

a size reduction mill (for example: Comil™ run at a slow speed) equipped with a suitable size sieve in order to produce resilient (hard, flexible, less-friable) particles thereby avoiding excessive dry milling which produce fines. These granules can be obtained with an average particle size of 200  $\mu\text{m}$  and can be effectively taste masked by coacervation by phase separation to produce taste-masked particles with optimum size distribution (e.g., mean particle size of not more than 400  $\mu\text{m}$ ) for incorporation into tablets, which rapidly disintegrate in the buccal cavity with a smooth creamy mouthfeel.

**[0016]** It is still another embodiment of the invention to provide a method of blending taste-masked microcapsules with rapidly dispersing microgranules produced by granulating, without a conventional binder, a sugar alcohol or a saccharide or a mixture thereof, with an average particle size of not more than 30  $\mu\text{m}$  and a disintegrant, and other pharmaceutically acceptable excipients and compressing the blend into tablets which rapidly disintegrate (e.g., less than 120 seconds, preferably less than 60 seconds) in the buccal cavity.

**[0017]** It is yet another embodiment of the invention to provide a method to manufacture rapidly disintegrating tablets, which are characterized by the property that it is formed by compressing in a tablet press equipped with an externally lubricating system to pre-lubricate dies and punches and the tablet formulation otherwise being free of lubricant. Intrabuccally rapidly disintegrating tablets exhibit sufficient hardness and sufficiently low friability and are suitable for packaging in HDPE bottles and blister packs using conventional equipment for storage, transportation and commercial distribution.

#### DETAILED DESCRIPTION OF THE INVENTION

**[0018]** From pharmaceutical and practical points of view, the inventors have examined various methods of taste-masking before coming up with a method which has wider applicability and also evaluated methods of producing intrabuccally rapidly disintegrating tablets, which don't require a special pharmaceutical production technique and can be simply and easily produced by a normal equipment. As a result, the inventors have developed, as a convenient method for effectively taste-masking bitter drug particles producing microcapsules of most desired particle size distributions, which are suitable for incorporation into tablets having the property of rapidly disintegrating in the buccal cavity and leaving no aftertaste (good creamy mouthfeel instead).

The invention also provides a method of manufacturing pharmaceutical tablets, produced by mixing microgranules of a sugar alcohol such as D-mannitol or a saccharide such as lactose, each having an average particle diameter of not more than 30 $\mu$ m, preferably not more than 20 $\mu$ m and a disintegrant with one or more taste-masked microcapsules and other excipients (for example: flavor, color, sweetener etc.) and compressing the blend into rapidly disintegrating tablets, the tablet thus produced having the property that it is formed by compressing in a tablet press equipped with an externally lubricating system to pre-lubricate dies and punches and the tablet formulation otherwise being free of lubricant.

**[0019]** A method of manufacturing tablets in accordance with one embodiment of the invention, which rapidly disintegrate in the buccal cavity without leaving undesirable mouth feel comprises the following steps:

- (a) granulating a sugar alcohol or a saccharide, or a combination thereof, each of which has an average particle diameter of not more than 30  $\mu$ m with a disintegrant such as Crospovidone using water or an alcohol-water mixture at a ratio of 1:3 to 3:1, without the addition of a binder, in a typical high shear granulator, wet milling to produce a desired particle size distribution, and drying in a fluid bed equipment to produce dispersible microgranules with an average particle size of not more than 400  $\mu$ m (typically the average particle size of not more than 300  $\mu$ m);
- (b) granulating a bitter active pharmaceutical ingredient and optionally one or more pharmaceutically acceptable diluents such as mannitol, lactose and microcrystalline cellulose with at least one polymeric binder such as modified starch and hydroxypropylmethylcellulose with a viscosity of 100 cps or higher, which imparts resilient, characteristics to the dried granules and wet milling using a size reduction mill such as Comil<sup>TM</sup> equipped with an appropriate sieve size to produce granules with a desired particle size distribution in order to avoid excessive dry milling which typically results in fines undesirable from the taste-masking point of view;
- (c) microencapsulating these resilient granules (mean size: 200  $\mu$ m or less) by coacervation in cyclohexane containing ethylcellulose to produce effectively taste-masked microcapsules with a desired particle size distribution (average particle size of not more than 400  $\mu$ m,

- typically not more than 300  $\mu\text{m}$ ) wherein the average membrane thickness is in the range of 30% to 50% by weight of the coated granules;
- (d) blending dispersible microgranules of step (a) with taste-masked microcapsules of step (c), and other acceptable ingredients such as a flavoring agent, a coloring agent, a sweetener and additional disintegrant in sufficient quantities to provide a therapeutically effective unit dose; and
- (e) compressing into tablets using a conventional rotary tablet press equipped with an external lubrication system to pre-lubricate the dies and punches, wherein the ratio of effectively taste-masked microgranules to dispersible microgranules is in the range of 1:1 to 1:10, preferably 1:2 to 1:5 approximately.

[0020] The term 'drug', 'active' or 'active pharmaceutical ingredient' as used herein is meant to include any therapeutic active agent indicated for oral administration such as macrolide antibiotic agents, analgesics, antidepressants, antihistamines, antihypertensives, antimigraine agents, proton pump inhibitors, antipsychotic agents, antiemetic agents, antiparkinson agents, and H<sub>2</sub> antagonists. In one embodiment, the drug candidates include ranitidine, cimetidine, clarithromycin, sumatriptan, lansoprazole, caffeine, cetirizine and their salts thereof. The active, in one embodiment has a particle size less than about 50 microns and is present in the tablet in an amount of about 0.01 to 30% by weight. In one embodiment the active has a particle size less than about 25 microns.

[0021] Polymers which impart resilient characteristics to the dried microgranules, include hydroxypropylcellulose (Klucel LF from Aqualon) modified starch (e.g., Starch 1551 and Starch 1500, commercially available from National Starch and Colorcon, respectively) and hydroxypropyl methylcellulose with a viscosity of 100 cps or more (e.g., Methocel K100LV or Metolose K400 commercially available from Dow Chemical and Shin Etsu Chemicals, respectively) alone or in combination with a widely used binder such as PVP (polyvinylpyrrolidone), hydroxypropylcellulose and hydroxypropyl methylcellulose with a viscosity of 15 cps or less (Methocel E5 or E15 and Pharmacoat 603 or 606 commercially available from Dow Chemical and Shin Etsu Chemicals, respectively).

**[0022]** Polymers suitable for microencapsulation of bitter drugs include ethylcellulose, cellulose acetate phthalate, hydroxypropyl methylcellulose phthalate depending on solubility in water or cyclohexane. No plasticizer is needed for forming membranes on active cores for effective taste-masking. One method for microencapsulating microgranules of the active to impart effective taste-masking characteristics is coacervation by phase separation of ethylcellulose in cyclohexane. Examples of such a coacervation process are disclosed in US Patent No. 6,139,865, which is incorporated in its entirety by reference.

**[0023]** One or more sugar alcohols and/or saccharides with an average particle size of not more than 30  $\mu\text{m}$  and a disintegrant are granulated with approximately 20-25% water in a high shear granulator, wet milled, dried in a fluid bed equipment to produce rapidly dispersible microgranules of desired particle size (average particle size of not more than about 300  $\mu\text{m}$  in accordance with methods disclosed in USP Application No. 200100114340 published on August 16, 2001). The sugar alcohol may be selected from the group consisting of mannitol, sorbitol, xylitol, maltitol and the like while the saccharide may be selected from the group consisting of lactose, sucrose, maltose or as a mixture of two or more, each of which is characterized by an average particle size of not more than about 30  $\mu\text{m}$ . In one embodiment the sugar alcohol and/or saccharide is present in the tablet in an amount of about 30 to 70% by weight.

**[0024]** A disintegrant is selected from the group consisting of crospovidone (crosslinked PVP), sodium starch glycolate, crosslinked sodium carboxymethyl cellulose, calcium silicate and low substituted hydroxypropyl cellulose. The disintegrant is typically present in the tablet in an amount of about 1 to 10% by weight. The disintegrant has a particle size less than about 30 microns in one embodiment.

**[0025]** In addition to coated microgranules of the active(s) in appropriate quantities, dispersible microgranules, and additional disintegrant as needed, the tablet produced in accordance with the embodiments of the present invention may contain suitable flavors, sweeteners, permissible colorants as needed. A lubricating agent such as magnesium stearate is not typically blended with this compression mix; but the punches and dies are pre-lubricated with a fine mist of the lubricant using an external lubrication system. Thus the hydrophobic lubricant is only present in trace quantities and that too on the tablet surface. This act of external lubrication permits rapid

penetration of the saliva in the mouth into the tablet core resulting in rapid disintegration/dispersion of the tablet into granules. These granules soaked in the saliva are carried down the throat into the stomach where the drug is released for maximum efficacy. The act of blending the lubricant with the compression mix and tableting using a conventional tablet press is also an embodiment of the present invention.

**[0026]** It is to be understood that while the invention has been described in conjunction with the preferred specific embodiments thereof, that the description above as well as the examples which follow below are intended to illustrate and not limit the scope of the invention. Any modification within the scope of the invention will be apparent to those skilled in the art to which the invention pertains.

Example 1 (Comparison):

**[0027]** Dispersible Microgranules: The dispersible microgranules comprise a sugar alcohol such as mannitol and a disintegrant. 6.65 kg of mannitol with an average particle size of approximately 10  $\mu\text{m}$  (Pearlitol 25 from Roquette, France) was blended with 350 g of crosslinked povidone (Crospovidone XL 10 from ISP) in a high shear granulator (GMX 25 from Vector) and granulated with sufficient amount of purified water (approximately 1.6 kg) and wet milled using Comil (from Quadro) and dried in a fluid bed drier, Glatt GPCG 5. The dispersible microgranules thus obtained has an average particle size of approximately 160  $\mu\text{m}$ .

**[0028]** Ranitidine Granulation: 400 g of ranitidine HCl was blended with 360 g of mannitol with an average particle size of not more than 25  $\mu\text{m}$ , 40 g of low viscosity hydroxypropyl methylcellulose (Methocel E5) and granulated with purified water. The wet mass was milled using a Comil and dried in the oven at 40°C for 3 hours.

**[0029]** Microencapsulation: The granules thus obtained were suspended in a solution of cyclohexane containing ethylcellulose with a viscosity of approximately 100 cps and polyethylene at approximately 80°C and membrane coated by properly cooling (coacervation). The microencapsulated granules were washed and dried. The granules (friable with 40% fines when tested by the friability test procedure) were found to undergo attrition due to agitation in the coacervation tank. The microcapsules thus obtained exhibited poor taste masking.

Example 2:

[0030] Ranitidine Granulation: 400 g of ranitidine HCl was blended with 360 g of mannitol with an average particle size not more than 25  $\mu\text{m}$ , 40 g of hydroxypropyl methylcellulose with an average viscosity of 400 cps and granulated with an aqueous solution of low viscosity hydroxypropyl methylcellulose (Methocel E5). The wet mass was milled using a Comil and dried in the oven at 40°C for 3 hours. The granules thus obtained were rigid/less friable with a desired particle size distribution (range: most particles in the range of 140-300  $\mu\text{m}$ ).

[0031] Microencapsulation: These granules were taste-masked by coacervation following the procedure given in Example 1. The microcapsules thus obtained contained largely intact granules and exhibited improved taste masking. The Laser light scattering and palatability testing suggests that the microcapsules with most desired particle size distribution (average particle size: 368  $\mu\text{m}$ ) exhibits an improved taste-masking.

[0032] Tableting: Dispersible microgranules (59.5%) were blended with taste-masked microcapsules (30.5%) and other pharmaceutical acceptable ingredients, such as flavor, sweetener, colorant, and additional disintegrant in sufficient quantity to provide a therapeutically effective unit dose (75 mg ranitidine), in a twin shell V-blender for a sufficient time to get homogeneously distributed blending for compression. Unit dose was measured on an analytical balance and compressed into tablet (weighing approximately one gram with a disintegration time of 45-60 seconds) at an optimized compression force on a carver press.

[0033] Dissolution Testing: Both microcapsules and tablets were tested for dissolution using USP Apparatus 2 (paddles@ 50 rpm) in 900 mL medium at 37°C and percentage of drug released was determined by HPLC. The results are presented in the table below:

## Drug released %

Time	Microcaps (966-DLG-183)	[0034] Tablet (984-VS-133-D)
5 min	8	67
10 min	24	85
20 min	48	92
30 min	60	97
45 min	70	100
60 min	77	100
120 min	87	100

Example 3:

Granulation: 651 g of ranitidine HCl was blended with 49 g of hydroxypropyl methylcellulose with an average viscosity of 400 cps and granulated with purified water. The wet mass was milled using a Comil and dried in the oven at 40°C for 3 hours. The granules thus obtained were rigid/less friable with a desired particle size distribution (range: most particles in the range of 200-400 µm).

[0035] Microencapsulation: These granules were taste-masked by coacervation following the procedure given in Example 1. The microcapsules thus obtained contained largely intact granules and exhibited improved taste masking. The Laser light scattering and palatability testing suggests that the microcapsules with most desired particle size distribution (average particle size: 400 µm) exhibits an improved taste-masking.

[0036] Tableting: Dispersible microgranules (73.9%) were blended with taste-masked microcapsules (16.1%) and other pharmaceutical acceptable ingredients, such as flavor, sweetener, colorant, and additional disintegrant in sufficient quantity to provide a therapeutically effective unit does, in a twin shell V-blender for a sufficient time to get homogeneously distributed blending for compression. Unit dose (approximately 1 g) was measured on an analytical balance and compressed into tablet at an optimized compression force on a carver press.

[0037] Dissolution testing: Microcapsules and tablets were tested for dissolution using USP Apparatus 2 (paddles@ 50 rpm) in 900 ml medium at 37°C and percentage of drug released was determined by HPLC. The results are presented in the table below:

**Drug Released %**

<b>Time</b>	<b>[0038] Microcaps (1008-KKQ-094-B-1)</b>	<b>[0039] Tablet (984-VS-133-C)</b>
5 min	11	43
10 min	27	63
20 min	47	77
30 min	57	84
45 min	68	88
60 min	74	90
120 min	89	94

Example 4:

[0040] Granulation: 600 g of ranitidine HCl was blended with 66.7 g of modified starch, Starch 1500 from Colorcon and granulated with purified water. The wet mass was milled using a Comil and dried in the oven at 40°C for 3 hours. The granules thus obtained were rigid/less friable with a desired particle size distribution (range: most particles in the range of 140-300  $\mu\text{m}$ ).

[0041] Microencapsulation: These granules were suspended in cyclohexane containing ethylcellulose with a viscosity of approximately 100 cps and polyethylene at approximately 80°C and membrane coated by properly cooling (coacervation). The microencapsulated granules were washed and dried. The microcapsules thus obtained contained largely intact granules and exhibited excellent taste-masking.

[0042] Tableting: Dispersible microgranules (68.9%) were blended with taste-masked microcapsules (20.1%) and other pharmaceutical acceptable ingredients, such as flavor, sweetener, colorant, and additional disintegrant in sufficient quantity to provide a therapeutically effective unit does, in a twin shell V-blender for a sufficient time to get homogeneously distributed blending for compression. Unit dose weighing approximately one gram was measured on an analytical balance and compressed into tablet at an optimized compression force on a carver press.

[0043] Dissolution testing: Both microcapsules and tablets were tested for dissolution using USP Apparatus 2 (paddles@ 50 rpm) in 900 mL medium at 37°C and percentage of drug released was determined by HPLC. The results are presented in the table below:

**Drug Released %**

Time	[0044] Microcaps (1029-DLG-006)	[0045] Tablet (1008-KKQ-134-C-AdvaTab)
5 min	12	42
10 min	27	63
20 min	45	80
30 min	54	86
45 min	63	91
60 min	68	93
120 min	80	96

Example 5:

[0046] Dispersible Microgranules: The dispersible microgranules comprise a sugar alcohol such as mannitol and a disintegrant. 152 kg of mannitol with an average particle size of approximately 10  $\mu\text{m}$  (Pearlitol 25 from Roquette, France) was blended with 8 kg of crosslinked povidone (Crosppovidone XL 10 from ISP) in a high shear granulator (GMX 600 from Vector) and granulated with sufficient amount of purified water (approximately 32 kg) and wet milled using Comil (from Quadro) and dried in a fluid bed drier, Glatt GPCG 200. The dispersible microgranules thus obtained has an average particle size of approximately 160  $\mu\text{m}$ .

[0047] Granulation: 5.0 kg of ranitidine HCl was blended with 600 g of modified starch, Starch 1500 from Colorcon and granulated with purified water in high shear mixer GMX 25 (from Vector). The wet mass was milled using a Comil and dried in the oven at 40°C for 3 hours. The granules thus obtained were hard/non-brittle with a desired particle size distribution (average particle size: 150  $\mu\text{m}$ ).

[0048] Microencapsulation: These granules were suspended in cyclohexane containing ethylcellulose with a viscosity of approximately 100 cps and polyethylene at approximately 80°C and membrane coated by properly cooling (coacervation). The microencapsulated granules were

washed and dried. The microcapsules thus obtained contained largely intact granules with an average particle size of 150  $\mu\text{m}$  and exhibited excellent taste-masking.

**[0049] Tableting:** Dispersible microgranules (5.4 kg) were blended with taste-masked microcapsules (1.06 kg from lots (1029-DLG-16 and 1029-DLG-17)) and other pharmaceutical acceptable ingredients, such as flavor, sweetener, colorant, and additional disintegrant in sufficient quantity to provide a therapeutically effective unit does, in a twin shell V-blender for a sufficient time to get homogeneously distributed blending for compression. Tablets weighing approximately 1 g were compressed using a production scale Hata Tablet press equipped with Matsui external lubrication system at an average hardness of 5.5 and 6.9 kP, respectively.

**[0050] Dissolution testing:** Microcapsules and tablets were tested for dissolution using USP Apparatus 2 (paddles@ 50 rpm) in 900 mL medium at 37°C and percentage of drug released was determined by HPLC. The results are presented in the table below:

**Drug Released %**

Time	Microcaps		Tablets 984-VS-152-2 (Hardness: 7.8 kP)
	1029-DLG-016	1029-DLG-017	
5 min	8	4	27
10 min	23	15	47
20 min	42	33	65
30 min	52	44	75
45 min	63	53	80
60 min	70	62	82
120 min	81	75	90

**Example 6:**

**[0051] Compressible Microcaps:** The microcapsules obtained in Example 4 were provided with a compressible coating of an aqueous dispersion of ethylcellulose (a fracture resistant, compressibility enhancing coating at 4% weight gain) in the fluid bed equipment. The coated microcaps were dried and cured. The microcapsules thus obtained exhibited excellent taste-masking. The dissolution was not affected.

[0052] Tableting: Dispersible microgranules were blended with taste-masked microcapsules and other pharmaceutical acceptable ingredients, such as flavor, sweetener, colorant, and additional disintegrant in sufficient quantity to provide a therapeutically effective unit dose, in a twin shell V-blender for a sufficient time to get homogeneously distributed blending for compression. Unit dose was measured on an analytical balance and compressed into tablet at an optimized compression force on a carver press.

[0053] Dissolution testing: Microcapsules and tablets were tested for dissolution using USP Apparatus 2 (paddles@ 50 rpm) in 900 mL medium at 37°C and percentage of drug released was determined by HPLC. The results are presented in the table below:

Drug Released %		
Time	[0054] Microcaps (1029-DLG-015 / 904-MDS-151)	[0055] Tablets
5 min	7	24
10 min	21	45
20 min	39	63
30 min	50	74
45 min	58	85
60 min	66	88
120 min	80	98

Example 7:

[0056] Granulation: 500 g of sumatriptan succinate was blended with 56 g of hydroxypropyl methylcellulose, HPMC K100LV, Hypromellose K100LV from Dow Chemical and granulated with purified water. The wet mass was milled using a Comil and dried in the oven at 40°C for 3 hours. The granules thus obtained were rigid/less friable with a desired particle size distribution (range: most particles in the range of 200 - 360 µm).

[0057] Microencapsulation: These granules were suspended in cyclohexane containing ethylcellulose with a viscosity of approximately 100 cps and polyethylene at approximately 80°C and membrane coated by coacervation at two coating levels (lot# 1029-DLG-018 at 45% coating and lot# 1029-DLG-024 at 35% coating). The microencapsulated granules were washed and

dried. The microcapsules thus obtained contained largely intact granules and exhibited excellent taste-masking.

**[0058] Tableting:** Dispersible microgranules of both microcapsule batches were blended with taste-masked microcapsules and other pharmaceutical acceptable ingredients, such as flavor, sweetener, colorant, and additional disintegrant in sufficient quantity to provide a therapeutically effective unit does, in a twin shell V-blender for a sufficient time to get homogeneously distributed blending for compression. Unit dose was measured on an analytical balance and compressed into tablet at similar compression force on a carver press (100 mg (as sumatriptan base) tablets weighing 1200 mg, hardness: 8-9 kP and disintegration time: approximately 30 seconds).

**[0059] Dissolution testing:** Microcapsules were tested for dissolution using USP Apparatus 2 (paddles@ 50 rpm) in 900 ml medium (0.1N HCl with 0.1% sodium lauryl sulfate) at 37°C and percentage of drug released was determined by HPLC. The results are presented in the table below:

**Drug Released %**

<b>Time</b>	<b>[0060] Microcaps (1029-DLG-018) 45% Coating</b>	<b>[0061] Tablet (1034-KKQ-009- C-T) 45% Coating</b>	<b>[0062] Microcaps (1029-DLG-024) 35% Coating</b>	<b>[0063] Tablet (1029-DLG-024- T) 35% Coating</b>

**[0064] Friability Testing:**

**[0065] The table presents the friability data for Ranitidine HCl and Sumatriptan succinate microgranules of examples 1 to 5 and 7.**

**Friability**

<b>Example</b>	<b>Granulation batch</b>	<b>Friability (% fines generated)</b>
No 1	1008-KKQ-025-A	40
No 2	1008-KKQ-027-K	12
No 3	1008-KKQ-094-B	9
No 4	1008-KKQ-134-C	10
No 5	1008-KKQ-140-B-1	8
No 7	1034-KKQ-009-C	9

**[0066]** Fine powders of pharmaceuticals, ores, foods, ceramics, and other materials are often agglomerated in various industrial processes and used as granules to overcome difficulties in handling or processing. These agglomerates or granules are required to have various properties, depending on the end use. Above all, granules must have the property of maintaining their integrity during handling and processing. Granules must flow for easy handling and transportation, and that means granules must have proper shape and particle size distribution. Furthermore, granules must be strong enough to maintain their integrity, e.g. shape/size, i.e., should not break or attrition or should exhibit sufficient strength and sufficiently low friability to withstand attrition during handling or processing, such as microencapsulation. At the same time, the microcapsules produced from these granules must be capable of being compacted into tablets with minimal membrane fracture; otherwise, tablets may exhibit undesirable aftertaste.

**[0067]** Granule size can be evaluated using a set of sieves or using a laser light scattering instrument. However, there are no well-established methods or instrumental techniques for rapid/easy testing of granule strength. An in-house method for evaluation of friability of granules to be used for microencapsulation has been developed and described below. This is a measure of the friability or integrity of the granules under dynamic or usage conditions.

**[0068]** The new test method uses a sieve shaker, an apparatus for the measurement of particle size distribution, with a test sieve (typically 140 mesh screen with an opening of approximately 105  $\mu\text{m}$  or as appropriate depending on the particle size distribution of granules), a pan and grinding balls. During the testing, fines produced if the test sample is friable, pass through the

sieve and are collected in the pan. Typically 20 grams granules and 100 g of 7-mm diameter ceramic grind balls are placed on the sieve and are subjected to shaking at medium setting for 10 min. At the end of the test, the ceramic balls are separated, the sieve containing the test sample is weighed and % friability is calculated. Based on several measurements and visual and microscopic observations on the microcapsules produced using granules subjected to friability testing, a friability value of 15% is considered an upper limit for granules to be suitable for microencapsulation.
